

Effective Programming Practices for Economists

Scientific Computing

Visualizing optimizer histories

Janoš Gabler and Hans-Martin von Gaudecker

Motivation

- You rarely have a guarantee that an optimizer will work
 - Assumptions of convergence proofs might not hold in practice
 - You might get stuck in local optima
 - Floating point calculations are never exact
- But you can compare the performance of optimizers
 - Which one finds the lower function value?
 - Which one decreases the function more quickly?
- The `criterion_plot` makes this very easy!

Criterion plot

We assume you have done an optimization and the result is called `res`

Criterion plot

```
em.criterion_plot(res)
```

- First argument can be:
 - ``OptimizeResult``
 - path to log file
 - list or dict thereof
- Dictionary keys are used for legend

Criterion plot

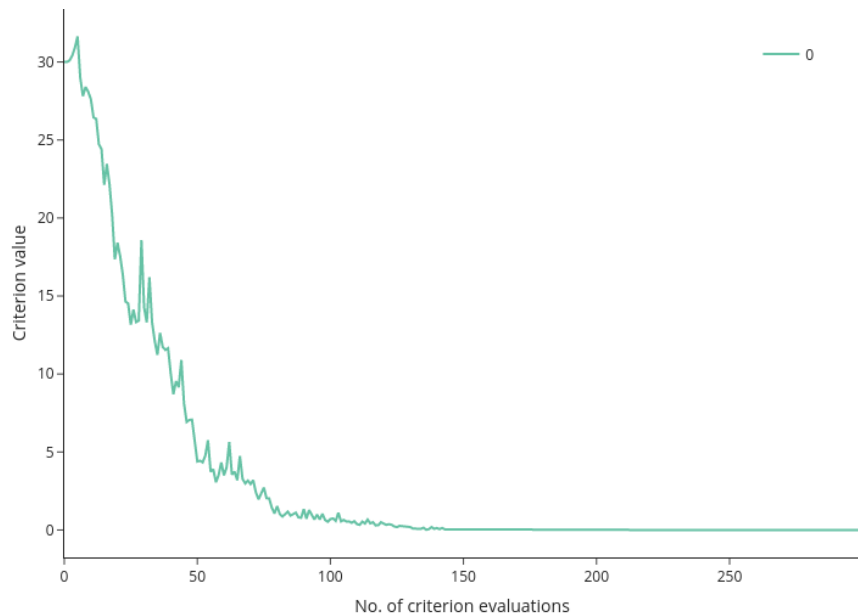

```
em.criterion_plot(res, monotone=True)
```

- **monotone=True** shows the current best value
- useful if there are extreme values in history

Criterion plot

```
em.criterion_plot(res, max_evaluations=300)
```

- **max_evaluations** limits the x-axis

Criterion plot for multiple optimizations

```
def sphere(x):  
    return x @ x  
  
results = {}  
for algo in ["scipy_neldermead", "nlopt_neldermead", "fides"]:  
    results[algo] = em.minimize(  
        sphere,  
        np.arange(10),  
        algorithm=algo,  
    )  
  
em.criterion_plot(results, max_evaluations=200)
```
